

Hydraulics | Hydrology | Geomorphology | Design

MEMORANDUM

Date:	1/21/2011
To:	Ann Van Leer, Chris Klein (San Diego Earth Works)
From:	John Stofleth, Chris Bowles, Chris Campbell (cbec Inc.)
Project:	08-1032 Rose Creek Watershed Restoration Opportunities Analysis
Subject:	Appendix C – Technical Memorandum for Data Collection and Hydrodynamic Model Development on Rose and San Clemente Creeks

BASELINE DATA COLLECTION

cbec performed a stream network field assessment and collected baseline data to observe and document the conditions of the watershed stream network. The field assessment encompassed the Rose Canyon main stem as well as the San Clemente main stem from I-805 to Mission Bay. The field assessment included photographic documentation at key observation points, hydraulic field surveys, stream bed sediment characterization, and water level monitoring. A summary of the procedures used to collect these data are provided below.

Hydraulic Field Surveys

cbec conducted a hydraulic field survey as a part of the baseline data collection effort and was used primarily in the development of the hydraulic model. This effort involved the collection of cross sectional topographic data of the low flow channel and the adjacent floodplain as well as other key features such as bridges and culverts. Hydraulic roughness (Manning's n) values associated with relative densities in vegetative cover and channel bedforms were also observed as a part of this effort and ranged from 0.02 to 0.1. Figure 1 displays the locations of the surveyed cross sections. The surveyed data were prepared in California State Plane (CASP) 1983 Zone 6 (feet) and NAVD 88 vertical datum (feet).

Streambed Sediment Characterization

cbec characterized the size of the streambed sediments within the project reach in an effort to analyze the sediment mobility of the corridor under existing and future rehabilitation conditions. The location of sediment sampling is shown by Figure 2. The sediment samples were analyzed for particle size distribution (PSD) and these results are presented in Figures 3-8. The sediment size data (PSD) were compared to velocity data derived from the hydraulic model,

in conjunction with published maximum incipient velocity to initiate sediment transport, to determine sediment mobility thresholds for Rose Creek and San Clemente Creek (see section 3.8 of the report that accompanies this memorandum) (San Diego Earth Works, 2010).

Water Level Data Collection

Continuous water level (stage) data was also collected at six key locations, as shown by Figure 9, within the project reach beginning in mid January 2010. These data are referenced to the NAVD 88 vertical datum and are displayed in Figures 10-15. The reason for collection of these data was for model validation.

MODEL DEVELOPMENT

A HEC-RAS (RAS) 1-dimensional hydraulic model was developed for approximately 11 miles of Rose and San Clemente Creeks within the RCW from I-805 to Mission Bay. Model development was facilitated by using HEC-GeoRAS, which is a GIS interface for pre-processing model inputs (i.e., cross sections) and post-processing model outputs (i.e., inundation maps). Modeled flows include the 2-, 5-, 10-, 25-, 50-, and 100-year storm events.

Topography

Topography used in the hydraulic model was developed using cross sectional surveys of the low flow channel and adjacent floodplains, collected as described in Section 2.2 of the accompanying report (San Diego Earth Works, 2010). Measured cross sections were taken at approximately 500 to 1,000 feet intervals. The locations of these cross sections are shown in Figure 1. Figures 16-103 displays a cross-sectional view of these topographic data. These data were supplemented with a 1999 topographic dataset developed by the City and County of San Diego (SANGIS). This primarily involved incorporating topographic data to extend the length of the surveyed cross sections across the valley floor. This dataset was collected and processed to an accuracy suitable to develop 2-foot contours. All data were prepared in California State Plane (CASP) 1983 Zone 6 (feet) and NAVD 88 vertical datum (feet).

Hydraulic Structures

Bridges and culverts that were incorporated into the model geometry include Genesee Avenue and Regents Road. Other hydraulic features associated with the concrete lined flood control channel downstream of the confluence were also incorporated. Data used to develop these structures were collected during the hydraulic field survey, while portions of the concrete flood control channel downstream of the confluence were derived from the SANGIS topographic dataset.

Hydraulic Roughness

Hydraulic roughness (Manning's n) values that correspond to the density of vegetative cover and channel bed forms were estimated during the hydraulic field survey using published guidelines (Chow, 1959). These values ranged from 0.02 to 0.1. Figures 16-103 displays a cross-sectional view of these topographic data with the associated Manning's n values.

Model Boundary Conditions

An HSPF hydrologic model of the RCW developed for the City of San Diego by Everest International Consultants (City of San Diego PUD, 2010) was utilized to derive unsteady flow boundary conditions for the hydraulic model. This model utilized hourly rainfall data from Lindberg Field for a 36 year period of record (1970-2006), soils permeability data, land use data and topographic data to produce unsteady flow hydrographs (hourly) for each of the sub-watersheds within the RCW for the 2-, 5, 10-, and 25-year return interval storm events. cbec performed a statistical analysis (flood frequency – USGS Bulletin 17b) using the annual peak discharges output from the terminus of this model to calculate the flow magnitude (recurrence interval) for a given storm event. These peak flows are listed in Table 2 below. Due to the limited period of record and the lack of extreme hydrologic events that occurred within the simulated period, the FEMA prescribed flows were selected for the 50- and 100-year flood events.

Table 2: Results of Flood Frequency Analysis using HSPF Model Output for the 2- to 25-Year Return Interval Events

Annual Exceedance Probability	Flood Event	Peak Discharge (cfs)
0.5	2	2,406
0.2	5	3,264
0.1	10	3,817
0.04	25	4,501
0.02	50 ¹	8,100
0.01	100 ¹	12,000

¹ FEMA prescribed flow were selected for the 50- and 100-year return interval flood events.

The hydraulic model includes a total of 14 boundary conditions for 2- to 25-year return interval events. Of these 14 boundary conditions, 13 were unsteady flow inputs derived from the HSPF hydrologic model. The hydraulic model includes two unsteady flow inputs immediately downstream of I-805. The remaining 11 flow inputs were modeled as lateral or uniform lateral inflows along Rose and San Clemente Creeks. The downstream boundary is a water surface elevation that represents an average tide condition (6.0 ft) according to FEMA guidelines. The locations of the boundary conditions are as shown in Figure 104 and are displayed graphically in Figures 105-136.

Model Limitations

The hydraulic model was developed as a tool to test the restoration feasibility of potential sites within the RCW, with a primary focus from I-805 to the confluence. The model is intended to be used as a planning tool to aid in the concept level development of potential restoration alternatives and as a baseline tool for the development of a final design of selected restoration alternatives.

However, the hydraulic model was constructed at the watershed scale. The topographic data used to construct the model was collected at 500 to 1000 foot intervals and not at a scale appropriate for analyzing the *final design* of particular restoration scenarios. Additional topographic and hydraulic roughness data should be incorporated into the project reach when the selected restoration projects are to be implemented. Alternatively, hydrologic data could be extracted from the existing model to serve as the boundary conditions for a separate hydraulic model that needs to be developed for analysis of the final design of a particular restoration site. The hydraulic model in its current state is not intended to be used for flood prediction / mapping purposes, according to FEMA guidelines. Several updates to the lower portion of the model should be implemented in order for it to be used as a flood prediction / mapping tool. These additional updates may include a denser network of topographic cross sectional data and the implementation of certain hydraulic structures that exist within the flood control channel downstream of the confluence.

The hydraulic model developed for this study utilized topographic data collected as a part of the hydraulic field survey, while the SANGIS topography was used to map inundation results produced from the model. The SANGIS dataset is of adequate resolution to perform these delineations outside of the low-flow channel; however, the low-flow channel represented in this dataset does not provide adequate resolution for hydraulic model development or mapping purposes. The maximum inundation extents from the modeled results in this study typically fall outside the low-flow channel within the areas of interest; therefore, the SANGIS topographic dataset was considered of adequate resolution for mapping inundation extents that fall outside the low-flow channel. Caution should be used when interpreting inundation extents that fall within the low-flow channel (especially in heavily vegetated areas).

RESULTS

Inundation Mapping

HEC-GeoRAS was utilized to map the maximum inundation extents for the 2-, 5-, 10-, 25-, 50-, 100-year return interval flow events for existing and proposed restoration alternative conditions. These results were used to determine the frequency of inundation for portions of the floodplain under existing and proposed project conditions. Figures 137-145 display existing condition inundation mapping from I-805 to Mission Bay for the 2-, 10-, 25- and 100-year events. Inundation mapping for the proposed conditions is included in section 5.4 of the main report at each of the proposed restoration sites (San Diego Earthworks, 2010).

Water Surface Profiles

HEC-GeoRAS was utilized to calculate the maximum water surface elevations for the 2-, 5-, 10-, 25-, 50-, 100-year return interval flow events for existing conditions and the proposed restoration alternative. Figures 148-153 display existing and proposed alternative maximum water surface profiles from I-805 to Mission Bay for the 2-, 5-, 10-, 25-, 50-, 100-year return interval flow events.
